

SIAP 2026 application

To: Accelerator@cbk.gov.kw

Applicant: Sulaiman Almkhaizeem

Initiative: Haris — a locally deployable AI security gateway for controlled customer-case preparation

This document follows all fields in the [official September 2026 brief](#). Applicant statements are self-declared.

This is an individual proposal, not a licensing or sandbox application.

Applicant information

Full Name: Sulaiman Almkhaizeem

Nationality: Kuwaiti

Year of Birth: 2004

Email Address: sfalmukhaizeem@gmail.com

Contact Number: +965 50131232

Current Occupation: MSc Cyber Security student at City St George's, University of London, United Kingdom (September 2026–September 2027 expected).

Academic & Professional Background: I graduated from Queen Mary University of London in Electrical and Electronic Engineering and am studying MSc Cyber Security at City St George's, University of London. My team placed first in Warba Bank's completed ROWAD Innovation Program 6.0 in 2025, where I co-developed a fintech concept, built break-even models and assessed rollout and operational risks for senior stakeholders. I have no continuing direct or indirect attachment to a fintech company or financial institution. I am applying as an individual technical founder and am willing to participate in teamwork, mentoring and program milestones while studying in the UK.

Educational Qualification: BEng (Hons) Electrical and Electronic Engineering, Queen Mary University of London, Upper Second-Class Honours (2:1), awarded 9 July 2026. Currently pursuing MSc Cyber Security, City St George's, University of London, expected September 2027.

Field of Study: Electrical and Electronic Engineering and Cyber Security.

Professional Experience (if applicable): ROWAD Innovation Program 6.0, September–December 2025: member of the first-place team among six competing teams; fintech concept development, financial modelling, operational-risk analysis and stakeholder presentation. This was a completed competition, not continuing bank employment. No bank client or deployment is claimed for Haris.

Technical Skills: Python, C/C++, Linux, MATLAB, GitHub, Excel, embedded systems, automation, data analysis, technical writing and project coordination. Haris demonstrates authenticated access, authorization checks, data minimization, local inference, content-bound independent approval and tamper-evident evidence. Arabic and English are professional working languages.

Research Experience (if applicable): My real-time sound-localisation project used an 8051 microcontroller, C and TDOA. I designed and tested three prototypes, analysed 70 structured tests and documented faults, limitations and findings in a 105-page engineering report. Other projects include Python/IoT data automation and an autonomous line-following robot. Haris adds source-based research, threat modelling and reproducible security evaluation. No bank interviews, published research or field validation are claimed for Haris.

Proposal information

Selected Program Theme: Cybersecurity, Digital Trust & Resilience.

Initiative Summary: Haris is a locally deployable security gateway for one narrow banking workflow: an employee prepares a customer-review case with an AI model, and a separate compliance reviewer decides whether to record the exact draft internally. The gateway determines customer scope from authenticated identity, minimizes data before inference, restricts model and tool access, and records the decision with Arabic and English reasons. The prototype uses synthetic data and a real local model, alongside an explicitly labelled deterministic adapter for reproducible control tests. It does not process payments, make credit or compliance determinations, contact customers, or execute model-generated tool calls. The demo ran locally on a Dell XPS 9320 with an i7-1280P, approximately 32 GB RAM and CPU-only Qwen inference; it produced a correct English case summary without a discrete GPU or paid API. Model quality remains limited and requires review. The accelerator work will validate the workflow and improve the controls with relevant experts.

Problem Statement: AI tools can receive sensitive customer information and untrusted source material during staff workflows. If a model is given broad retrieval or action authority, manipulated or mistaken output can cross customer boundaries or trigger an action beyond the employee's entitlement. A later reviewer also needs to know which identity, policy and precise content authorized an action. CORF's AI-security, inference-data protection and auditability controls make this a relevant security problem. Local bank reports demonstrate AI adoption, but I have not established the frequency or commercial cost of this specific workflow. Haris provides a controlled way to test the technical boundary and obtain practical feedback before any bank deployment.

Innovative Aspects: The proposed contribution is the integration of one-customer scope, minimized local inference, independent approval bound to a content digest, and bilingual decision evidence in a runnable banking case workflow. Existing gateways, PII tools and guardrail libraries already implement many underlying capabilities. Haris does not claim a new detector or universal prompt-injection protection. Its differentiation must be validated through easier workflow integration and evidence reconstruction. The prototype exposes its failures: the fixed regression corpus includes missed attacks and a false positive, while the model remains unable to gain additional customer or tool authority. This makes the initiative practical to examine and improve within SIAP.

Current Stage of Development: Prototype. A local working application, synthetic demo, API, local-model route, automated security tests, fixed evaluation cases, responsive English/Arabic UI and evidence package are available. No bank production deployment, customer pilot, CBK approval or commercial traction is claimed.

Supporting material

The accompanying problem memo, pitch, business/regulatory case, source register, control map, threat model, measured results and source archive make the prototype reviewable. Participation is sought for structured feedback, mentoring and validation. No funding, licence, sandbox admission, implementation or adoption commitment is assumed.
